P8158 - Must Athletes be Tough? Effects of Athletic Identity and Resilience on Well-Being during COVID-19

Waveley Qiu, Yihan Qiu, Yuanyuan Zeng

2022-05-04

Motivation

- ► The onset of COVID-19 affected almost every sphere of work and leisure.
- ▶ We are interested in investigating the impact athletic identity may have on athletes' overall well-being, particularly as the context of a global pandemic may have dramatically impacted one's experience of playing a sport/being an athlete.

Resilience, Healthy Lifestyle, and Mental Health

- Resilience and healthy lifestyle are both characteristics that are associated with improved mental health.
- We hypothesize that the effect that being a devoted athlete has on overall well-being would be mediated through these two characteristics, and will endeavor to investigate the relationships between these variables as well.

Methodology

- 1. Conduct EFA and CFA to determine which observed variables underlie our latent variables of interest.
- 2. Evaluate reliability of the determined latent structures with Chronbach's alpha.
- 3. Construct SEM(s) to quantify the relationship between our constructed latent variables and mental health score.

Data: Athlete Mental Healthy Survey

The dataset we selected is from a study in which several surveys administered in the UK, after their first COVID-19 lockdown, including:

- ► Athletic Identity Scale (AIMS)
- The Brief Resilience Scale
- ► Mental Health Continuum Short Form (MHC-SF)

In total, 753 individuals were interviewed – we will focus our analysis on the 363 athletes represented in this study.

Latent Variable 1: Athletic Identity

First Order Factors	AIMS Items			
Social identity				
AIMS 1	I consider myself an athlete. CNSDR_ATH			
AIMS 2	I have many goals related to sport. SPRT_GOALS			
AIMS 3	Most of my friends are athletes. FRNDS_ATH			
Exclusivity				
AIMS 4	Sport is the most important part of my life. SPRT_IMPT			
AIMS 5	I spend more time thinking about sport than anything else. THINK_SPRT			
Negative affectivity				
AIMS 6	I feel bad about myself when I do poorly in sport. BAD_SPRT			
AIMS 7	I would be very depressed if I were injured and could not compete in sport. DPRS_SPRT			

Note: Participants respond to the 7-items of the Athletic Identity Measurement Scale (AIMS) on a Likert-type scale ranging from 1 (strongly disagree) to 7 (strongly agree).

Athletic Identity Scale (AIMS)

Latent Variable 1 (Athletic Identity): EFA

After conducting EFA, we first propose that there are three latent variables underlying the AIMS variables, structured as follows:

- external_identity (comprised of sprt_goals, cnsdr_ath, frnds_ath)
- internal_value (comprised of sprt_impt, think_sprt)
- negative_events (comprised of dprs_sprt, bad_sprt)

Latent Variable 1 (Athletic Identity): Reliability

Chronbach's alpha were reasonable for internal_value and negative_events (0.81 and 0.63, respectively), with no variables indicated that could be dropped to improve reliability.

However, for external_identity:

Since Chronbach's alpha for external_identity would improve significantly if frnds_ath is removed, we decided to remove this variable from the latent structure.

Latent Variable 1 (Athletic Identity): CFA

We hypothesized that there exists a second-order latent variable, athletic_identity, underlying the latent variables external_identity, internal_value, and negative_events. Conducting a CFA allows us to evaluate this hypothesis:

Latent Variables:

	Estimate	Std.Err	z-value	P(> z)
external_identity =~				. (1-1)
sprt_goals	0.677	0.073	9.247	0.000
cnsdr_ath	0.584	0.056	10.404	0.000
internal_value =~				
sprt_impt	0.627	0.109	5.728	0.000
think_sprt	0.840	0.166	5.077	0.000
negative_events =~				
dprs_sprt	0.625	0.078	8.053	0.000
bad_sprt	0.799	0.103	7.777	0.000
athlete_identity =~				
external_dntty	0.809	0.143	5.658	0.000
internal_value	1.396	0.374	3.729	0.000
negative_evnts	0.813	0.152	5.364	0.000

Fit statistics: CFI > 0.99, RMSEA < 0.05, $\chi^2=$ 0.514

Latent Variable 2: Resilience

	Please respond to each item by marking <u>one box per row</u>	Strongly Disagree	Disagree	Neutral	Agree	Strongly Agree
BRS 1	I tend to bounce back quickly after hard times	1	2	3	4	□ 5
BRS 2	I have a hard time making it through stressful events.	5	4	3	2	1
BRS 3	It does not take me long to recover from a stressful event. STRS_RCVR	1	2	3	4	 5
BRS 4	It is hard for me to snap back when something bad happens. SNAR_BACK	 5	4	3	2	1
BRS 5	I usually come through difficult times with little trouble.	1	2	3	4	5
BRS 6	I tend to take a long time to get over set-backs in my life. SET BACKS	5	4	3	2	1

The Brief Resilience Scale (BRS)

Latent Variable 2 (Resilience): EFA

After running EFA on 1- and 2- factor models, we find that the 1-factor model, containing all variables from the scale fits the best.

Latent Variable 2 (Resilience): Reliability

Latent Variable 2 (Resilience): CFA

```
Latent Variables:
                Estimate Std.Err z-value P(>|z|)
 resilience =~
   bounce
                  0.662
                         0.045 14.732
                                         0.000
                  0.852 0.052 16.419
                                         0.000
   strs evnt
                0.679 0.051 13.415
   strs_rcvr
                                         0.000
   snap_back
                0.814 0.048 17.031
                                         0.000
   difficult
                0.644 0.051 12.559
                                         0.000
   setbacks
                 0.828 0.046 17.954
                                         0.000
```

Fit statistics: CFI > 0.98, RMSEA < 0.08, $\chi^2 = 0.017$

Latent Variable 3: Healthy Lifestyle

We hypothesized that we could create a latent variable representing a healthy lifestyle using the following variables:

- fruit_veg: Five Fruit and Vegetables (Yes/No)
- smoking: Smoking Status (7-point Likert scale)
- hr_sleep: Hour Sleep (numeric variable)

Latent Variable 3 (Healthy Lifestyle): Reliability

Chronbach's alpha is very low for these variables, indicating that the variables hr_sleep, smoking, fruit_veg do not reliably measure the latent variable.

Since healthy_lifestyle is thus not reliably measured with these variables, we made the decision to exclude this latent variable from SEM analysis — treating this latent variable as a formative (rather than a reflective) construct might more accurately reflect its nature.

Outcome Variable: Mental Health Continuum Short Form (MHC-SF)

During the past month, how often did you feel	NEVER (O)	ONCE OR TWICE	ABOUT ONCE A WEEK	ABOUT 2 OR 3 TIMES A WEEK (3)	ALMOST EVERY DAY	EVERY DAY
1. happy						
2. interested in life				5	ik.	
3. satisfied		8				
that you had something important to contribute to society		č.			8	
5. that you belonged to a community (like a social group, or your neighborhood)		K				
that our society is becoming a better place for people like you					9	

Mental Health Continuum Short Form (MHC-SF)

Outcome Variable: MHC-SF

Three components of well-being are assessed:

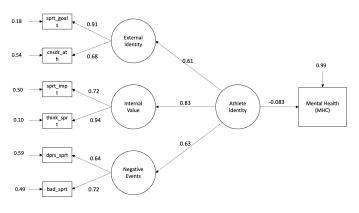

- Emotional
- Social
- Psychological

We will use the MHC-SF composite score (sum of all responses) as our outcome variable. Higher scores indicate greater levels of positive well-being.

SEM 1: Athletic Identity and MHC-SF

First, we constructed a SEM relating athletic identity to MHC-SF, without any mediating variable.

Model 1: Relationship between Athlete Identity and Mental Health (MHC) for Athletes

^{*}Standardized Path Coefficients

SEM 1: Athletic Identity and MHC-SF

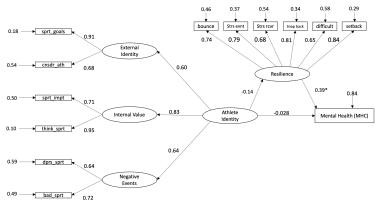

We found that though the estimated effect between athletic identity and MHC-SF is negative, indicating that a stronger athletic identity decreases overall well-being, the p-value associated with this value is 0.232.

Therefore, we conclude that there is **no** significant relationships between athletic identity and overall well-being

SEM 2: Resilience, Athletic Identity, and MHC-SF

We constructed another SEM to investigate the mediation effect of Resilience on causal relationship between athletic identity and MHC-SF.

Model 2: Relationship between Athlete Identity and Mental Health (MHC) Mediated by Resilience for Athletes

Standardized Path Coefficients Note: Value with * is significant at 0.05

SEM2: Resilience, Athletic Identity, and MHC-SF

We found that estimated effect between athletic identity and resilience is negative, indicating that stronger athletic identity increases resilience. Such effect is not significant.

The estimated effect between resilience and MHC-SF is positive, indicating that stronger resilience increases overall well-being. Such effect is significant at 0.05 significant level.

The indirect effect of athletic identity on MHC-SF through its effect on resilience is 0.14*0.39 = 0.0546. This indicates that increasing resilience by 0.39 leads to a 0.0546 increase in MHC-SF.
